

Definition of Speedup

2

If you are using n processors, your $Speedup_n$ is:

$$Speedup_n = \frac{T_1}{T_n}$$

where T_1 is the execution time on **one core** and T_n is the execution time on **n cores**. Note that Speedup_n should be > 1.

And your **Speedup Efficiency** $_n$ is:

$$Efficiency_n = \frac{Speedup_n}{n}$$

which could be as high as 1., but probably never will be.

However, Multicore is not a Free Lunch: Amdahl's Law

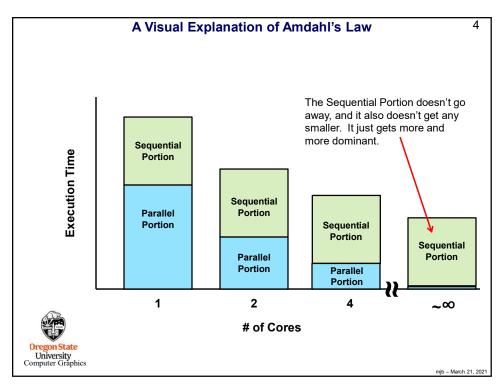

If you put in *n* processors, you should get *n* times Speedup (and 100% Speedup Efficiency), right? Wrong!

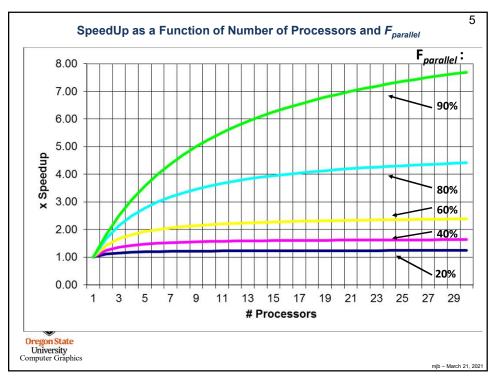

There are always some fraction of the total operation that is inherently sequential and cannot be parallelized no matter what you do. This includes reading data, setting up calculations, control logic, storing results, etc.

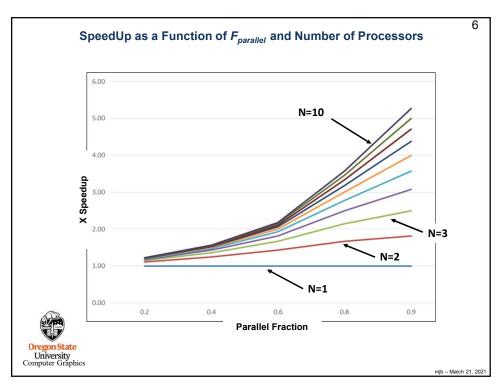

If you think of all the operations that a program needs to do as being divided between a fraction that is parallelizable and a fraction that isn't (i.e., is stuck at being sequential), then **Amdahl's Law** says:

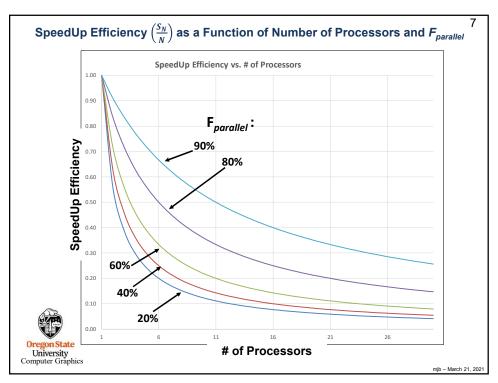

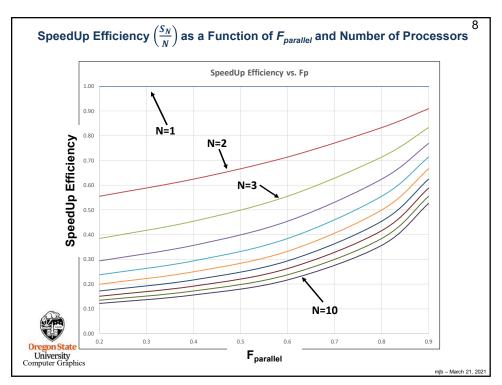

3

Amdahl's law says:

$$S = \frac{T_1}{T_n} = \frac{1}{\frac{F}{n} + (1 - F)}$$

$$\frac{1}{S} = \frac{F}{n} + (1 - F) = 1 + \frac{F - nF}{n}$$

$$\frac{1}{S} - 1 = F \frac{(1 - n)}{n}$$
Use this if you know the timing
$$\frac{1}{S} - 1 = F \frac{(1 - n)}{n}$$

Solving for F:

$$F = \frac{\frac{1}{S} - 1}{\frac{1 - n}{n}} = \frac{\frac{T_n - T_1}{T_1}}{\frac{1 - n}{n}} = \frac{\frac{T_1 - T_n}{T_1}}{\frac{1 - n}{n}} = \frac{n(T_1 - T_n)}{T_1(n - 1)} = \frac{n}{(n - 1)} \frac{T_1 - T_n}{T_1} = \frac{n}{(n - 1)} \left(1 - \frac{1}{Speedup}\right)$$

If you've got several (n,S) values, you can take the average (which is actually a least squares fit):

$$F_i = \frac{n_i}{(n_i - 1)} \frac{T_1 - T_{n_i}}{T_1}, i = 2..N$$

$$\overline{F} = \frac{\sum_{i=2}^{N} F_i}{N - 1}$$

10

9

Amdahl's Law can also give us the Maximum Possible SpeedUp

Note that these fractions put an upper bound on how much benefit you will get from adding more processors:

$$\max Speedup = \lim_{n \to \infty} Speedup = \frac{1}{F_{sequential}} = \frac{1}{1 - F_{parallel}}$$

Fparallel	maxSpeedup
0.00	1.00
0.10	1.11
0.20	1.25
0.30	1.43
0.40	1.67
0.50	2.00
0.60	2.50
0.70	3.33
0.80	5.00
0.90	10.00
0.95	20.00
0.99	100.00

A More Optimistic Take on Amdahl's Law: The Gustafson-Baris Observation

11

Gustafson observed that as you increase the number of processors, you have a tendency to attack larger and larger versions of the problem. He also observed that when you use the same parallel program on larger datasets, the parallel fraction, F_p , increases.

Let P be the amount of time spent on the parallel portion of an original task and S spent on the serial portion. Then

$$F_p = \frac{P}{P + S}$$
Parallel Serial Time Time

or
$$S = \frac{P - PF_p}{F_p}$$

Without loss of generality, we can set P=1 so that, really, S is now a fraction of P. We now have:

$$S = \frac{1 - F_p}{F_p}$$

11

A More Optimistic Take on Amdahl's Law: The Gustafson-Baris Observation

12

We know that if we multiply the amount of data to process by N, then the amount of parallel work becomes NP. Surely the serial work must increase too, but we don't know how much. Let's say it doesn't increase at all, so that we know we are getting an upper bound answer.

In that case, the new parallel fraction is: $F_p^{'} = \frac{P'}{P' + S} = \frac{NP}{NP + S}$

And substituting for P (=1) and for S, we have:

$$F_{p}' = \frac{N}{N+S} = \frac{N}{N+\frac{1-F_{p}}{F_{p}}}$$
